Electron and proton transfer reactions in photosynthetic reaction centers

Hiroshi Ishikita

石北 央

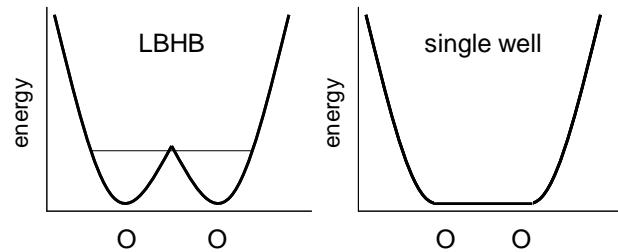

Low-barrier H-bonds
really exist?

Can we identify Low-barrier H-bond at the DFT level?

$$\text{LBHB: } pK_a(\text{donor}) = pK_a(\text{acceptor})$$

LBHB can be unambiguously identified in the potential-energy profile at the DFT level (with neither solving the nuclear Schrödinger equation nor considering dynamics)

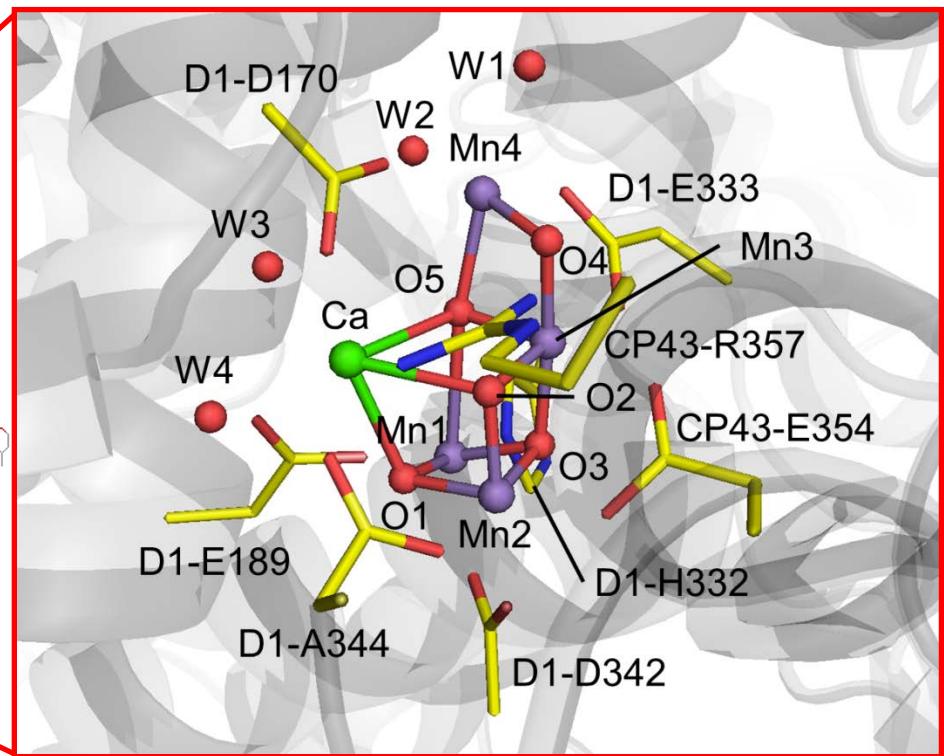

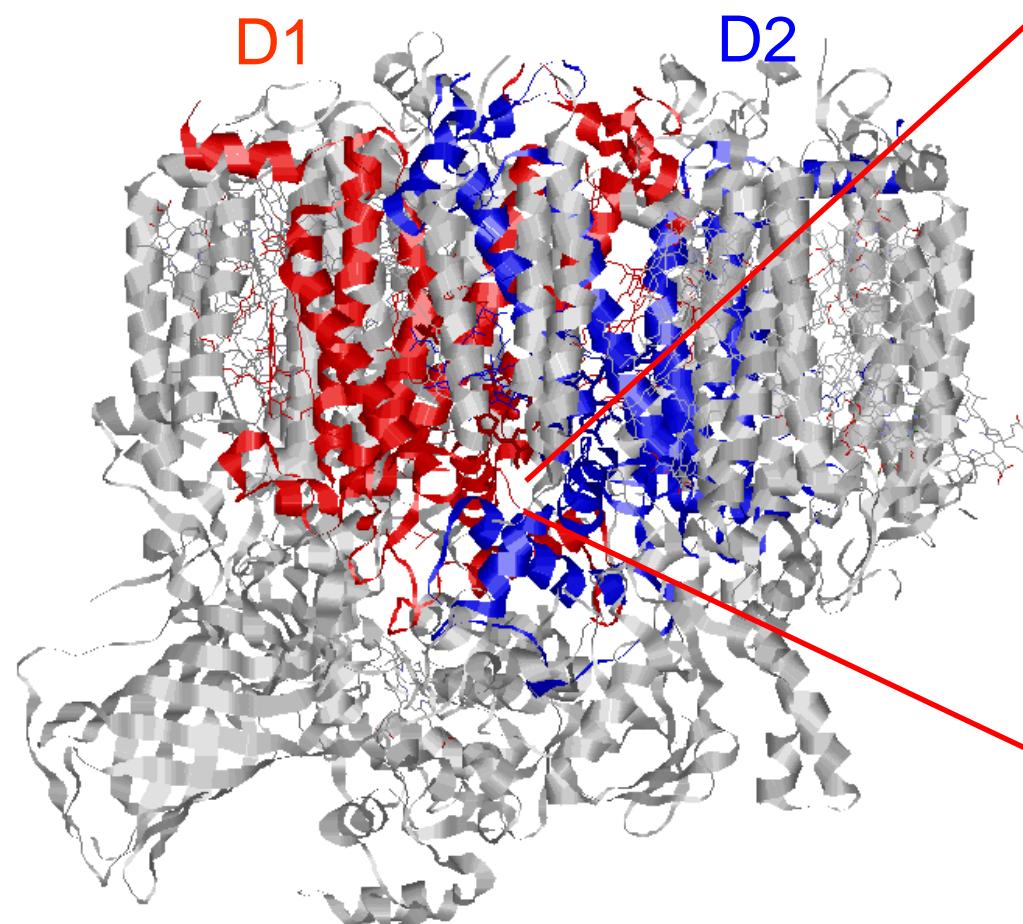

Does a low-barrier H-bond also exist
in a protein environment?

A short H-bond in photosystem II

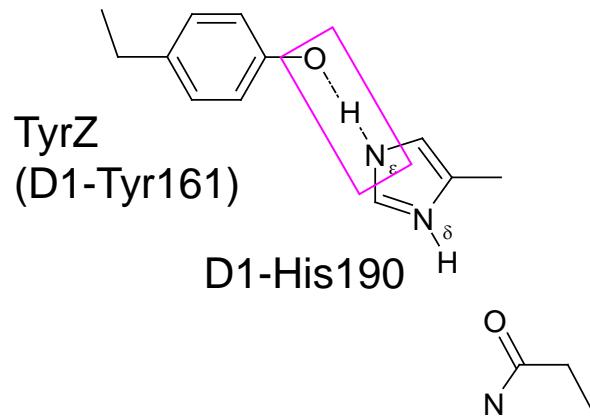

Light-driven water-splitting enzyme Photosystem II

2 substrate water molecules are catalyzed at the Mn_4CaO_5 cluster

QM/MM (Quantum Mechanics/ Molecular Mechanics)

Umena, Kawakami, Shen, Kamiya
(2011) *Nature* 473, 55

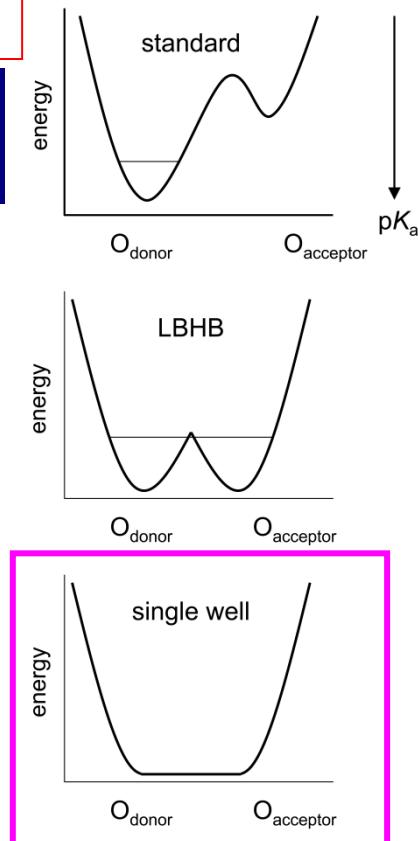

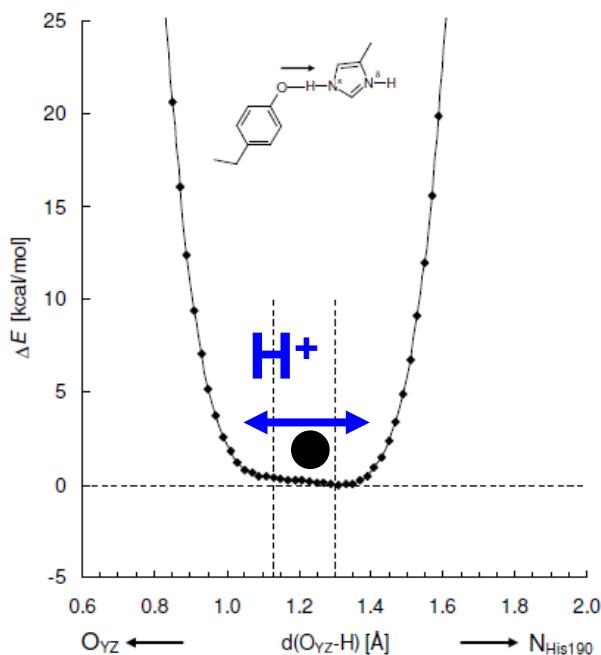

$O_{TyrZ}-N_{His190} = 2.46 \text{ \AA}$
Remarkably short!

QM/MM calculations (B3LYP / LACVP**+)

(PDB) $O_{Tyr}-N_{His}$ distance = 2.46 Å

(calc.) $O_{Tyr}-N_{His}$ distance = 2.47 Å

The unusually short H-bond seems to be quantumchemically reasonable!

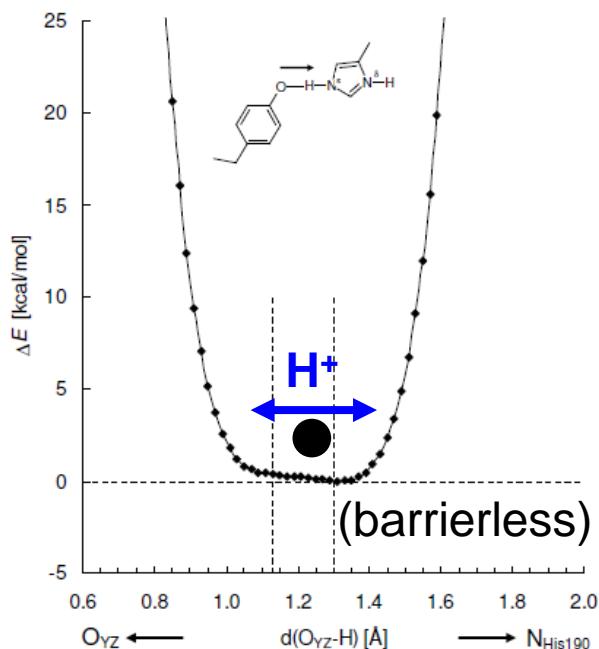

This is why TyrZ...His can mediate proton-coupled electron transfer (PCET)

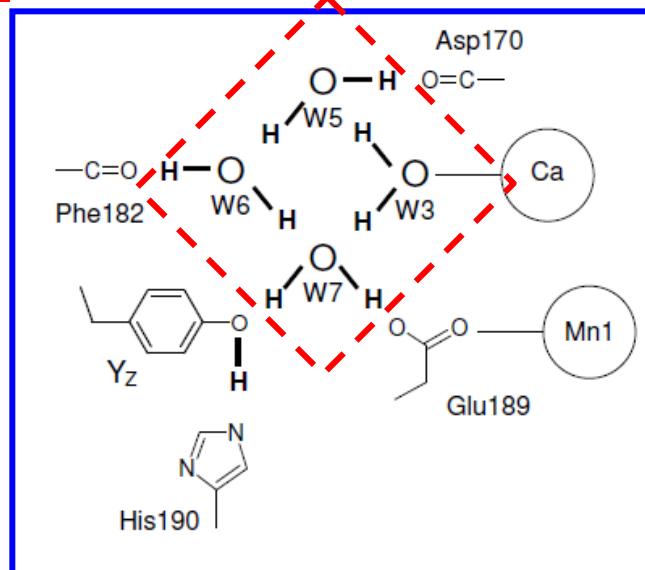

What makes the TyrZ...His190 distance so short?

QM/MM calculations (B3LYP / LACVP**+)

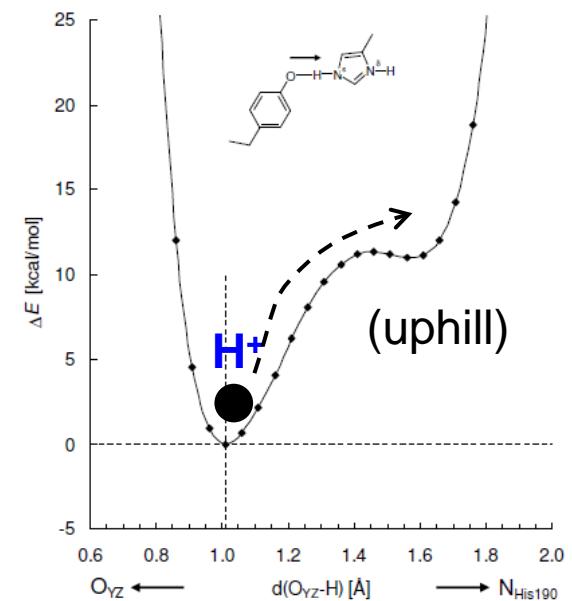

O_{Tyr} - N_{His} distance = 2.47 Å

polar environment in PSII

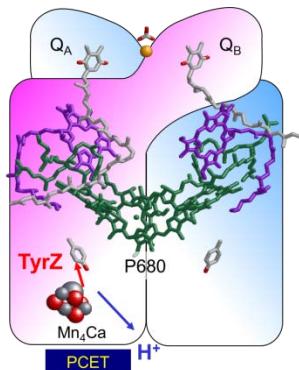

O_{Tyr} - N_{His} distance = 2.71 Å

Removal of waters

Single-well

A cluster of water molecules near Mn_4Ca
→ Matching pK_a between TyrZ and His190

Standard
(asymmetric double-well)

The barrier-less H-bond facilities PCET

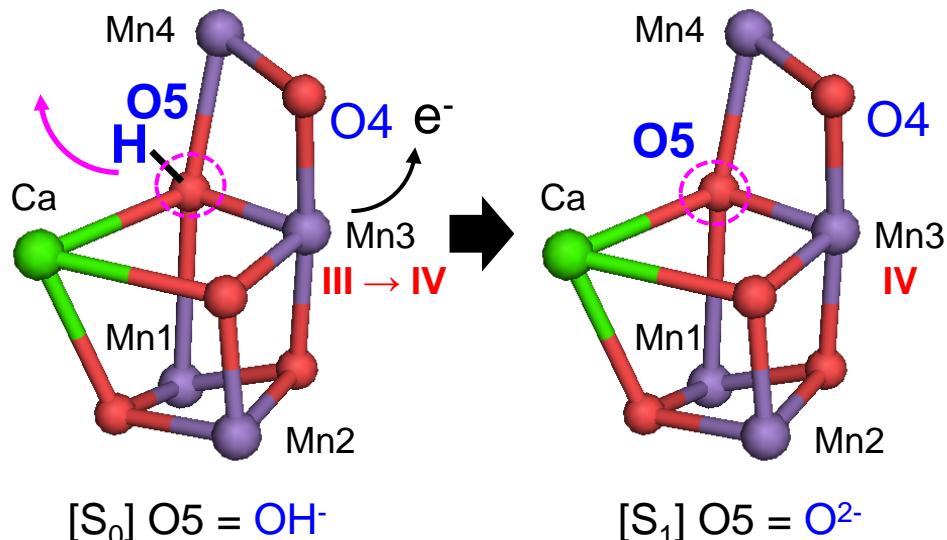

H^+ release from H_2O in photosystem II

Identification of the H⁺ releasing site in the S₀-to-S₁ transition

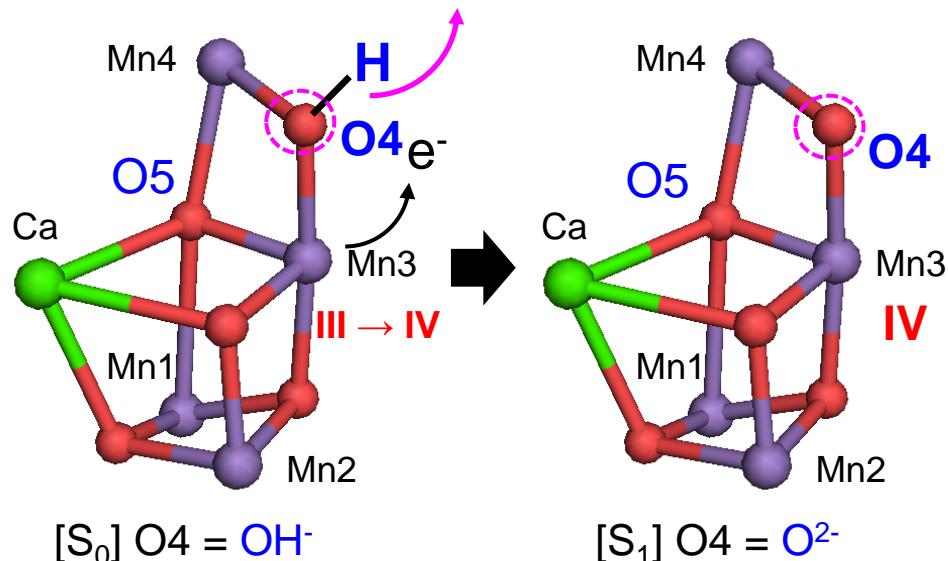

“O5 or O4”, which is the substrate?

Note: in the oxidation of the crystal structure, the substrate water is considered to be OH-.

1) Substrate = O5

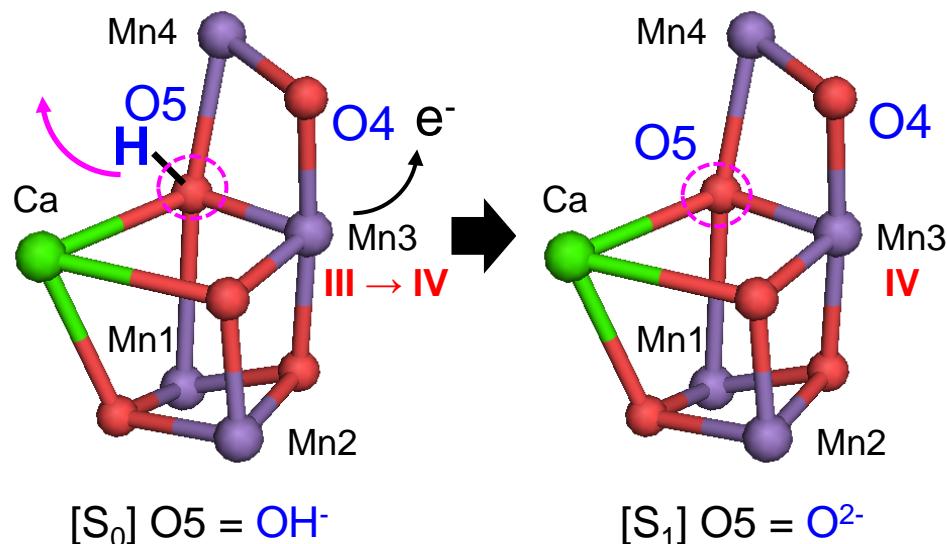

2) Substrate = O4

Identification of the H⁺ releasing site in the S₀-to-S₁ transition

1) Substrate = O5

O5 is close to Ca²⁺ and is apparently interesting...

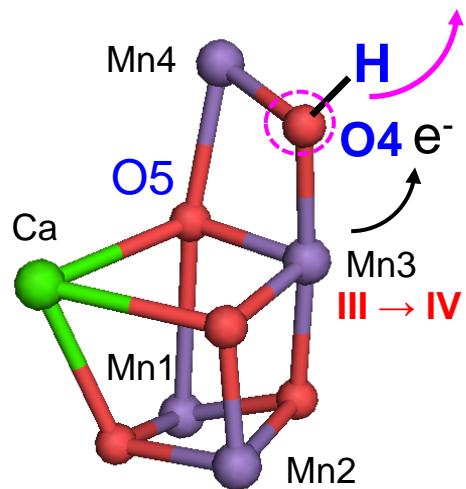

However, O5 has no H-bond partner in the crystal structures
(Umena et al. *Nature* 2011, Suga et al. *Nature* 2015)

no proton transfer from O5
(The activation energy for proton release must be high)

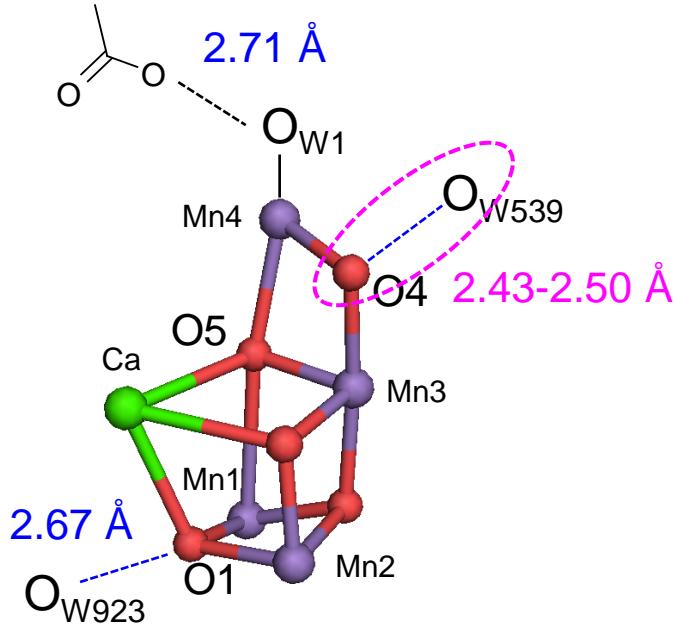

H-bonds of the Mn_4CaO_5 cluster

2) Substrate = O_4^-

$[S_0] O_4^- = OH^-$

D1-Asp61

Umena, Kawakami, Shen, Kamiya (2011) *Nature* 473, 55

The $O_4 \dots O_{W539}$ bond is very short (<2.5 Å!)

We focus on the $O_4 \dots O_{W539}$ H-bond

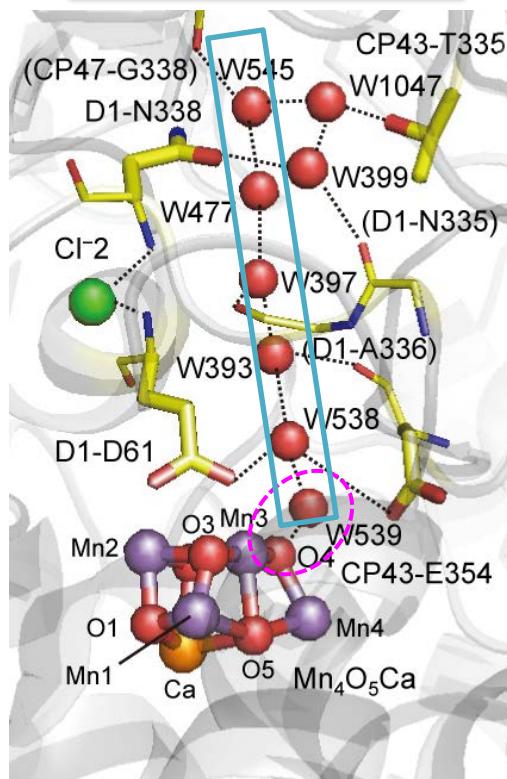

Changes in the H-bond potential in the S_0 -to- S_1 transition

O4 is linked with the O4-water chain via W539

X-ray

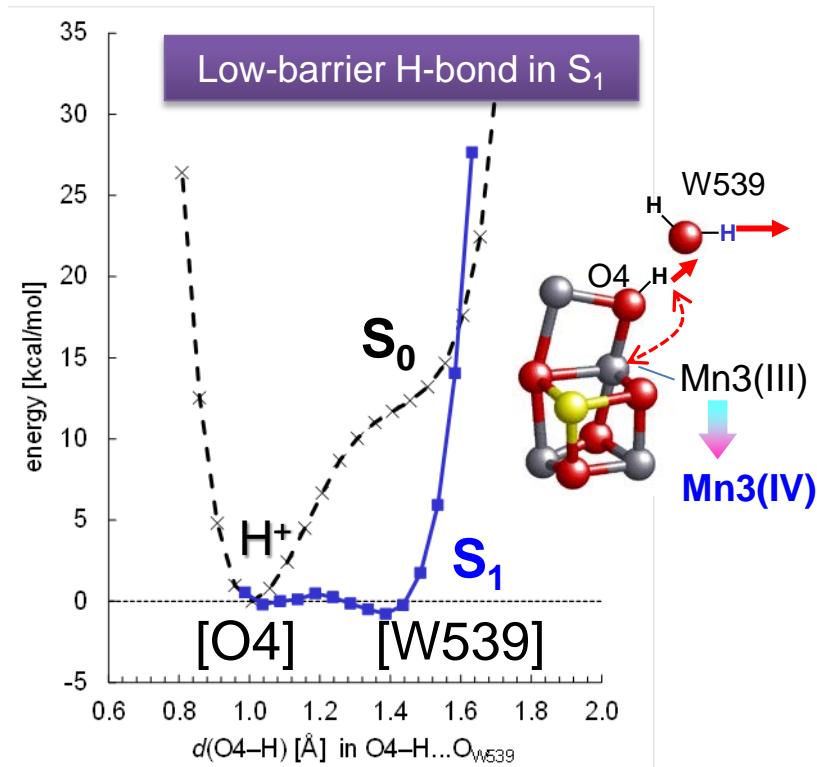

O4...O_{W539} distances:
2.43-2.50 Å (Umena 2011)

O4-water chain

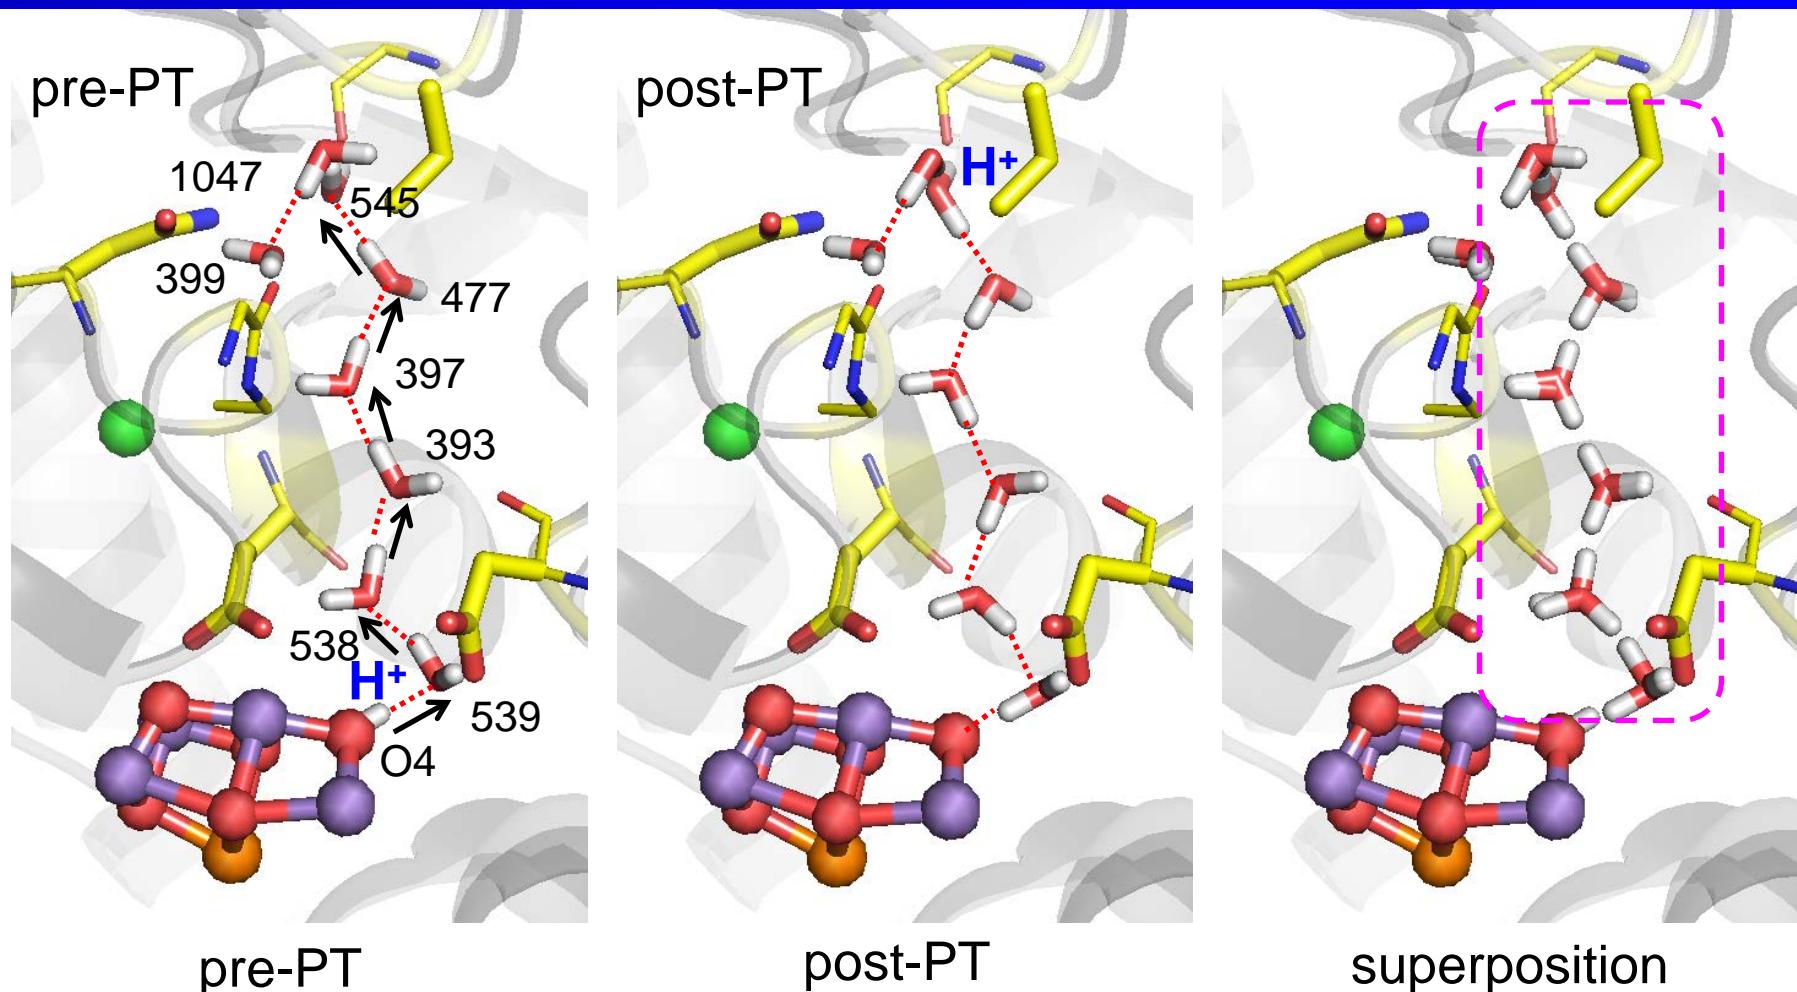

QM/MM

2.55 Å in S_0 (Saito 2015)
2.45 Å in S_1 (Saito 2015)

H-bond pattern: before and after PT in the S_0 -to- S_1 transition

O atoms did not move during H^+ transfer

The activation energy is low

- O4 is the deprotonation site
- The O4-water chain is the proton transfer pathway

Experimental support for the O4-water chain being used in S₀-to-S₁

Time-resolved infrared spectroscopy

The S₀-to-S₁ transition:

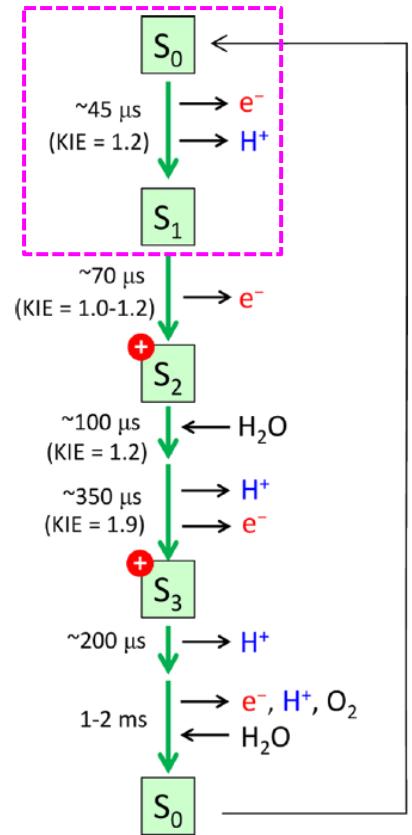

“the highest rate among the four S-state transitions.”

“The high PCET rate with a relatively small KIE value (~1.2)”

“This result is more consistent with the O4-H structure (Saito et al.) than the O5-H one.”

Simizu, Sugiura, Noguchi. (2018) *J. Phys. Chem. B* 122, 9460

The time-resolved infrared spectroscopy supports
“O4 is the deprotonation site in the S₀-to-S₁ transition”

Conclusions:

- O4 is the deprotonation site (= substrate water)
- The O4-water chain is the proton transfer pathway
